

Object-Oriented Programming

Object-Oriented Programming

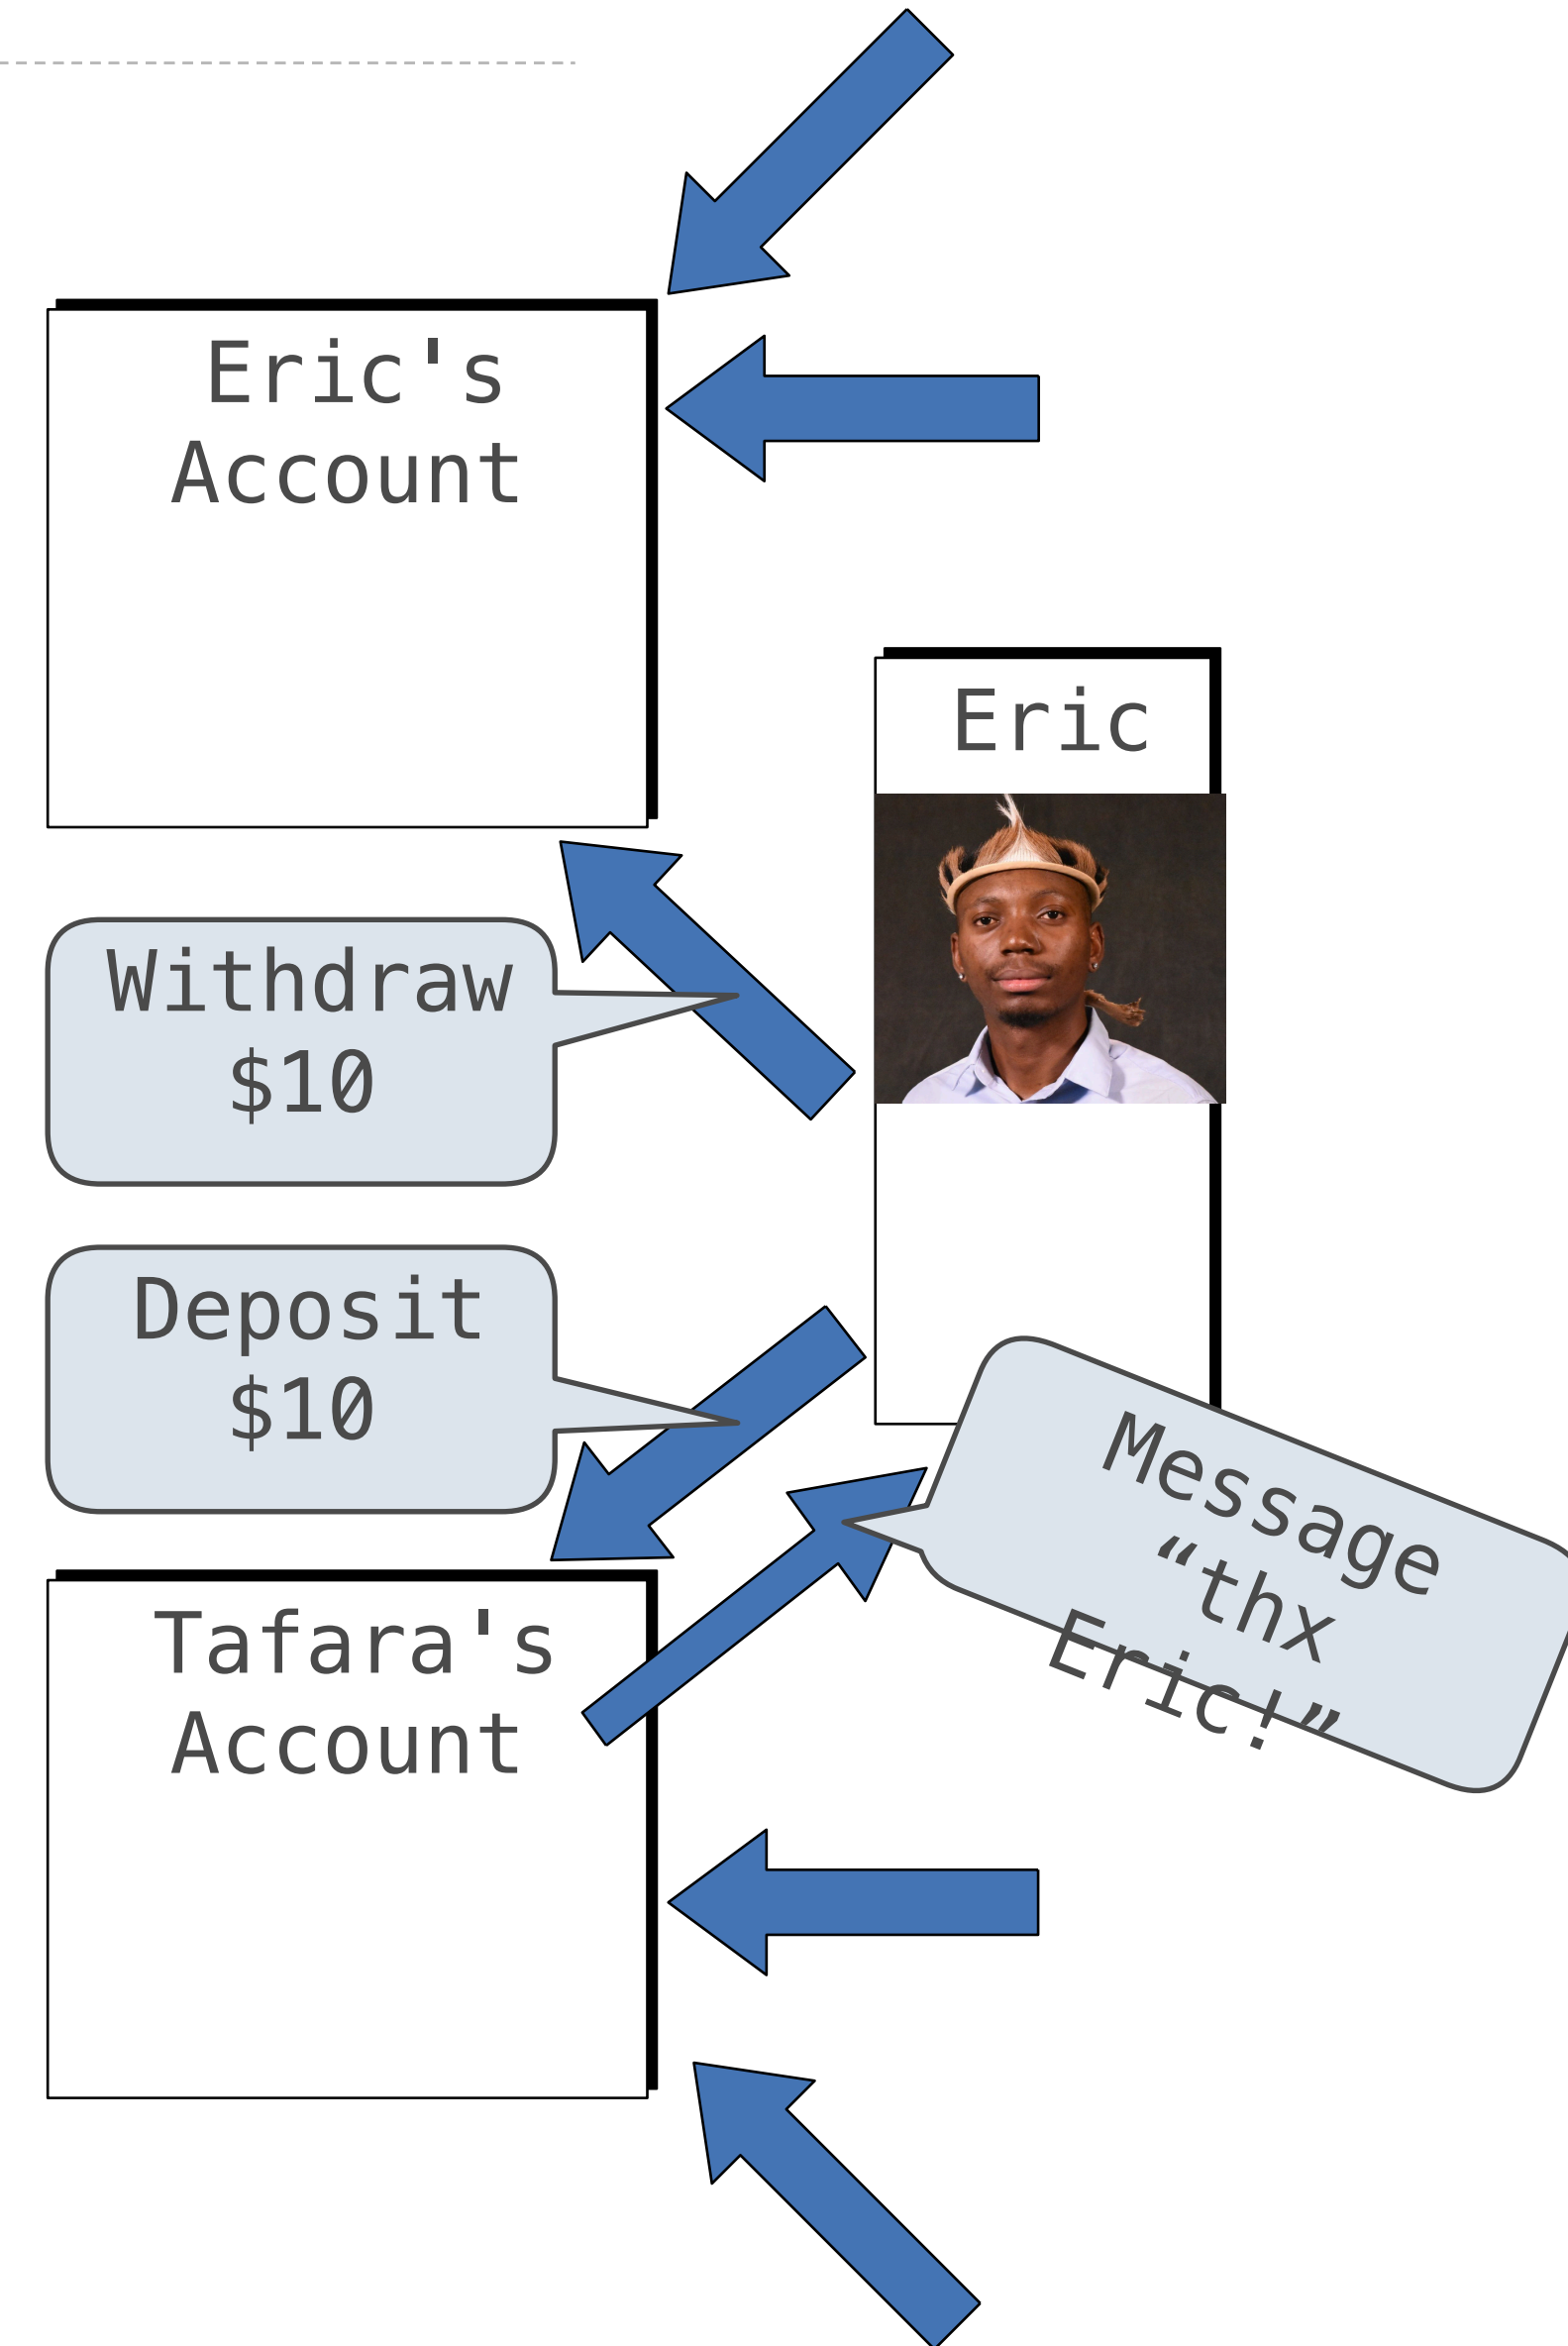

A method for organizing programs

- . Data abstraction
- . Bundling together information and related behavior

A metaphor for computation using distributed state

- . Each object has its own local state
- . Each object also knows how to manage its own local state, based on method calls
- . Method calls are messages passed between objects
- . Several objects may all be instances of a common type
- . Different types may relate to each other

Specialized syntax & vocabulary to support this metaphor

Classes

A class describes the general behavior of its instances

Idea: All bank accounts have a `balance` and an account `holder`; the `Account` class should add those attributes to each newly created instance

```
>>> a =  
Account('Eric')  
>>> a.holder  
'Eric'  
>>> a.balance  
0
```

Idea: All bank accounts should have `withdraw` and `deposit` behaviors that all work in the same way

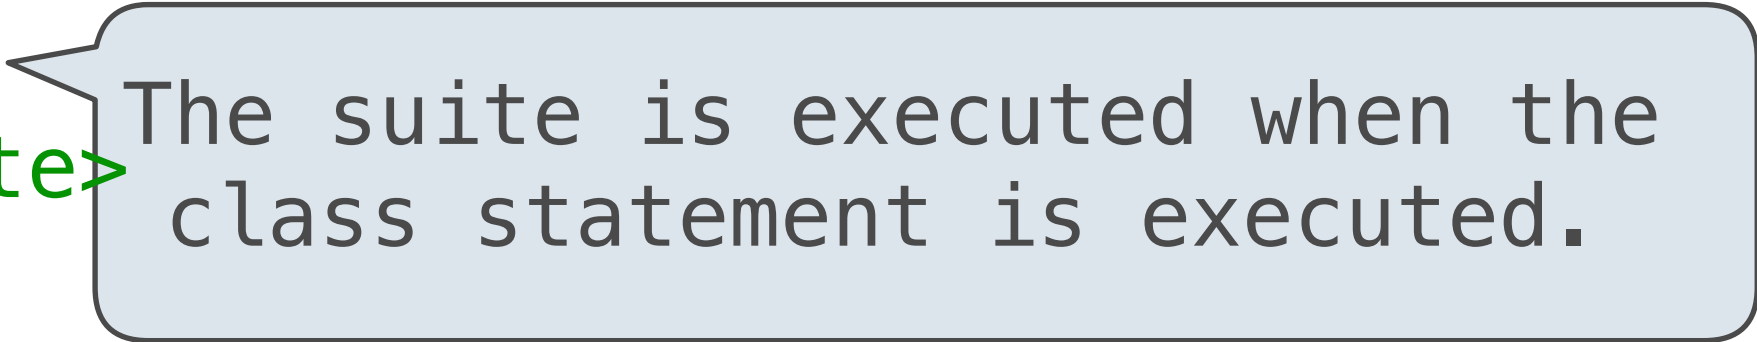

```
>>> a.deposit(15)  
15  
>>> a.withdraw(10)  
5  
>>> a.balance  
5  
>>> a.withdraw(10)  
'Insufficient  
funds'
```

Better idea: All bank accounts share a `withdraw` method and a `deposit` method

Class Statements

The Class Statement

```
class  
<name>:  
    <suite>
```

The suite is executed when the class statement is executed.

A class statement creates a new class and binds that class to `<name>` in the first frame of the current environment
Assignment & def statements in `<suite>` create attributes of the class (not names in frames)

```
>>> class Clown:  
...     nose = 'big and red'  
...     def dance():  
...         return 'No thanks'  
...  
>>> Clown.nose  
'big and red'  
>>> Clown.dance()  
'No thanks'  
>>> Clown  
<class '__main__.Clown'>
```

Object Construction

Idea: All bank accounts have a **balance** and an account **holder**;
the **Account** class should add those attributes to each of its instances

```
>>> a = Account('Drogon')
>>> a.holder
'Drogon'
>>> a.balance
0
```

When a class is called:

1. A new instance of that class

An account instance
balance: 0 holder:
'Drogon'
2. The `__init__` method of the class is called with the new object as its first argument (named `self`), along with any additional arguments provided in the call expression

`__init__` is
called a
constructor

```
class Account:
    def __init__(self,
account_holder):
    self.balance = 0
    self.holder = account_holder
```

Object Identity

Every object that is an instance of a user-defined class has a unique identity:

```
>>> a =  
Account('Eric')  
>>> b =  
Account('Tafara')  
>>> a.balance  
0  
>>> b.holder  
'Tafara'
```

Every call to Account creates a new Account instance.

There is only one Account class.

Identity operators "is" and "is not" test if two expressions evaluate to the same object:

```
>>> a is a  
True  
>>> a is not  
b  
True
```

Binding an object to a new name using assignment does not create a new object:

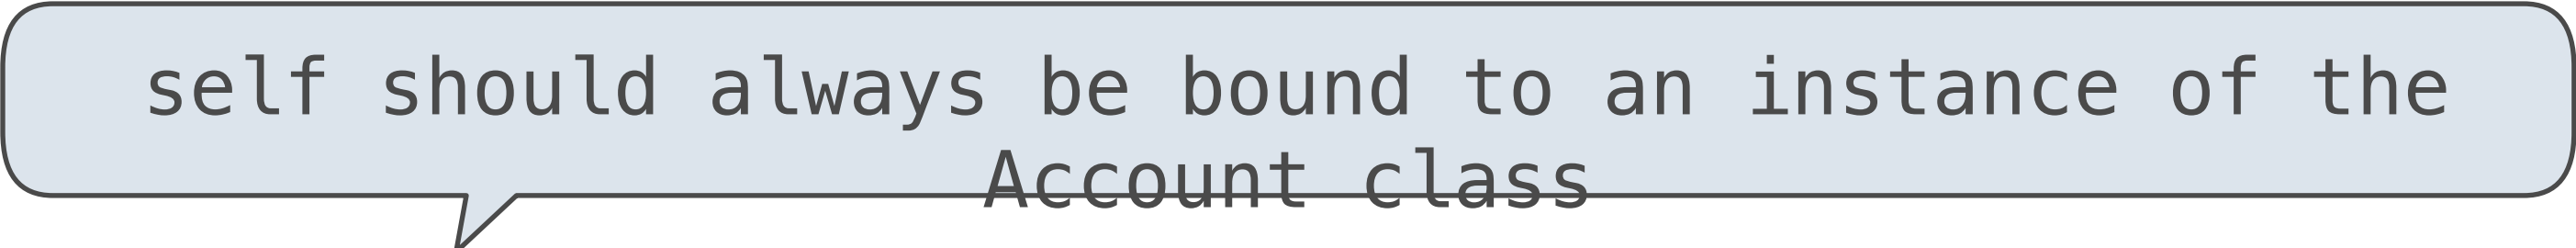

```
>>> c =  
a  
>>> c is  
a  
True
```

Methods

Methods

Methods are functions defined in the suite of a class statement

```
class Account:
    def __init__(self, account_holder):
        self.balance = 0
        self.holder = account_holder
    def deposit(self, amount):
        self.balance = self.balance + amount
        return self.balance
    def withdraw(self, amount):
        if amount > self.balance:
            return 'Insufficient funds'
        self.balance = self.balance - amount
        return self.balance
```

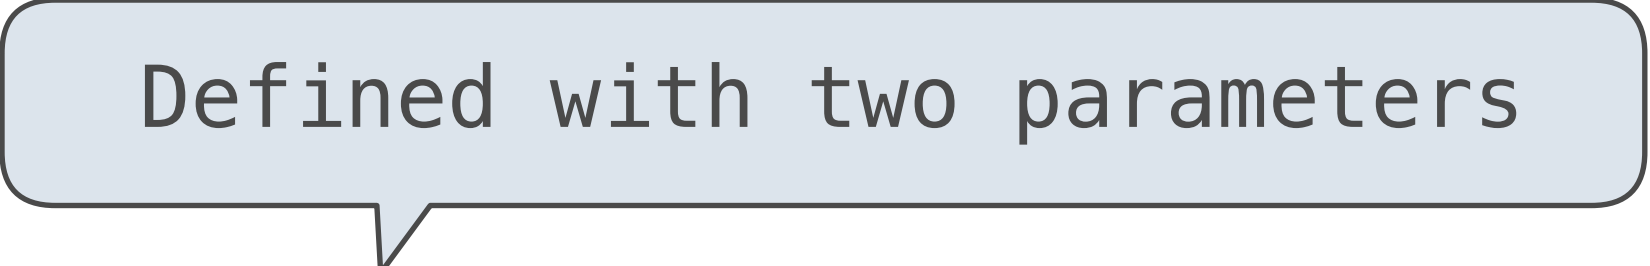

These def statements create function objects as always,
but their names are bound as attributes of the class

Invoking Methods

All invoked methods have access to the object via the `self` parameter, and so they can all access and manipulate the object's state

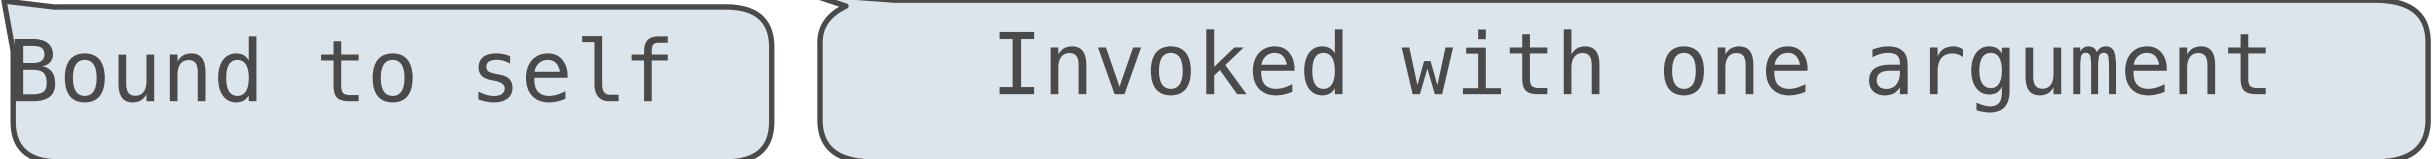

```
class Account
    ...
    def deposit( self, amount ):
        self.balance = self.balance + amount
        return self.balance
```

Defined with two parameters

Bound methods automatically supply the first argument during a function call

```
>>> drogon_account = Account('Drogon')
>>> drogon_account.deposit( 100 )
100
```

Bound to self

Invoked with one argument

Dot Expressions

Objects receive messages via dot notation

Dot notation accesses attributes of the instance or its class

```
<expression> .  
<name>
```

The `<expression>` can be any valid Python expression

The `<name>` must be a simple name

Evaluates to the value of the attribute looked up by `<name>` in the object that is the value of the `<expression>`

Attributes

(Demo
)

Accessing Attributes

Using `getattr`, we can look up an attribute using a string

```
>>> getattr(drogon_account,
'balance')
100
>>> getattr(drogon_account,
'deposit')
True
```

`getattr` and dot expressions look up a name in the same way

Looking up an attribute name in an object may return:

- . One of its instance attributes, or
- . One of the attributes of its class

Methods and Functions

Python distinguishes between:

- . *Functions*, which we have been creating since the beginning of the course, and
- . *Bound methods*, which couple together a function and the object on which that method will be invoked

Object Instance + Function = Bound Method

```
>>> type(Account.deposit)
<class 'function'>
```

```
>>>
type(drogon_account.deposit)
<class 'method'>
```

```
>>> Account.deposit(drogon_account, 912)
1012
```

```
>>> drogon_account.deposit(1007)
2019
```

Function: all arguments within parentheses

Method: instance before the dot and other arguments within parentheses

Looking Up Attributes by Name

`<expression> .
<name>`

To evaluate a dot expression:

1. Evaluate the `<expression>` to the left of the dot, which yields the object of the dot expression
2. `<name>` is matched against the instance attributes of that object; if an attribute with that name exists, its value is returned
3. If not, `<name>` is looked up in the class, which yields a class attribute value
4. That value is returned unless it is a function, in which case a bound method is returned instead

Class Attributes

Class attributes are "shared" across all instances of a class because they are attributes of the class, not the instance

```
class Account:

    interest = 0.02    # A class attribute

    def __init__(self, account_holder):
        self.balance = 0
        self.holder = account_holder

    # Additional methods would be defined here
```

```
>>> eric_account = Account('Eric')
>>> tafara_account = Account('Tafara')
>>> tafara_account.interest
0.02
>>> eric_account.interest
0.02
```

The `interest` attribute is *not* part of the instance; it's part of the class!

Summary

- Object-oriented programming (OOP) is a programming paradigm that emphasizes re-usability and distributed state: an object stores and modifies its own local state.
- Objects have attributes. Specifically, classes store “class attributes” that get passed down to instances as “instance attributes” that can be further customized per instance.
- When you construct an instance (a.k.a. call `__init__` using `<class>(<args>)`), the **functions** stored in the class become **bound methods**.
